Basis of Report

This document has been prepared by SLR Consulting Limited (SLR) with reasonable skill, care and diligence, and taking account of the timescales and resources devoted to it by agreement with Fearna Storage Limited (the Client) as part or all of the services it has been appointed by the Client to carry out. It is subject to the terms and conditions of that appointment.

SLR shall not be liable for the use of or reliance on any information, advice, recommendations and opinions in this document for any purpose by any person other than the Client. Reliance may be granted to a third party only in the event that SLR and the third party have executed a reliance agreement or collateral warranty.

Information reported herein may be based on the interpretation of public domain data collected by SLR, and/or information supplied by the Client and/or its other advisors and associates. These data have been accepted in good faith as being accurate and valid.

The copyright and intellectual property in all drawings, reports, specifications, bills of quantities, calculations and other information set out in this report remain vested in SLR unless the terms of appointment state otherwise.

This document may contain information of a specialised and/or highly technical nature and the Client is advised to seek clarification on any elements which may be unclear to it.

Information, advice, recommendations and opinions in this document should only be relied upon in the context of the whole document and any documents referenced explicitly herein and should then only be used within the context of the appointment.

1.0 Introduction

1.1 General

SLR Consulting Ltd (SLR) was commissioned by Fearna Storage Limited (the Applicant) to undertake a Peat Landslide Hazard and Risk Assessment (PLHRA) at the proposed Fearna Pump Storage Scheme (hereafter referred to as the “Proposed Development”). The Proposed Development is split into two separate areas which will be referred to throughout this report as the Pumped Storage Hydropower (PSH) site and the Southern Access Route (SAR). The location and layout of the Proposed Development are detailed on **Figure 12.1.1** and **Figure 12.1.2** with the red line defining ‘the site boundary’.

The methods adopted for the assessment follow the best practice guidance issued by the Scottish Government¹ for investigation, assessment and reporting for power infrastructure development in peat areas. The guidance provides a screening tool to determine whether a PLHRA is required.

The requirements to undertake a PLHRA are when blanket peat is present, slopes exceed 2° and the proposed infrastructure is located on peat, or when raised bogs are present. These conditions exist at the Proposed Development and therefore a PLHRA is required.

Where relevant, reference is also made to guidance published by the Scottish Environment Protection Agency (SEPA)² and wind farm construction good practice guidance³ where relevant to construction on peat.

The work has been undertaken by a team of Geotechnical Engineers and Geologists, with over 10 years’ experience in undertaking peat assessments. The team was led by a Chartered Hydrogeologist with 30 years’ consultancy experience and specialising in the assessment of soils, geology and water for renewable power projects in Scotland.

1.2 The Proposed Development

The Proposed Development would be situated within the boundaries of several landholdings approximately 25km to the west of Invergarry. Access to the Proposed Development during construction phase would be from the A87 along a route south of Loch Garry, passing through commercially forested areas before traversing open moorland to the PSH. The final section of access to the PSH would be along the existing public road, the C1144, which would be widened locally. The main PSH works, comprising the upper and lower reservoirs and associated works, are situated approximately 1km to the west of the Quoich Dam.

The Proposed Development would operate by transferring water between a lower reservoir, the existing Quoich reservoir, and an upper reservoir created by raising the level of Loch Fearna. The reservoirs would be connected by a system of underground waterways, with the turbines located in shafts within a powerhouse structure by the shore of the Quoich reservoir. The generating capacity of the scheme would be up to 1,800MW, with enough storage with the upper reservoir full to generate for approximately 20 hours at this capacity.

Full details Proposed Development are provided in **Chapter 2: The Proposed Development of the EIA Report**.

1.3 Scope and Objectives of Report

The purpose of this report is to consider the extent of peat and potential peat slide hazard at the Proposed Development and consider the potential impact to any development, such that areas of deep peat and areas at high risk of a peat slide can be avoided during the design phase. Further consideration is given to stability risks due to construction of the development and potential risks to receptors in a across the Proposed Development.

The peat stability assessment is primarily concerned with the influence of the peat on the development of the wind farm. The main objective is to assess the potential peat stability at the Proposed Development, identify areas of potential concern and identify mitigation measures to ensure the maintenance of peat stability before, during and after construction. All aspects of construction should be based on ensuring minimum disruption to the peat areas. The objectives have been achieved by completion of the following:

- a desk-based review of available reports which include geological, hydrological and topographical information;
- several phases of peat depth surveys;
- geomorphological mapping of the Proposed Development to identify the prevailing conditions influencing the potential for, or any evidence of, active, incipient or relict peat instability, including identification of the location and photographic record, as appropriate;
- reporting on evidence of any active, incipient or relict peat instability, and the potential risk of future instability, describing the likely causes and contributory factors;
- identification of potential controls to be imposed on the Contractors for the works to minimise the risk of peat instability occurring at the Proposed Development; and
- provide recommendations for further work or specific construction methodologies to suit the ground conditions at the Proposed Development to mitigate any unacceptable risk of potential peat instability.

Construction of the development would only increase the risk of peat slope instability if good geotechnical construction practice is ignored and it is a requirement of all renewable energy developments to follow a very carefully worded and designed Construction and Environmental Management Plan (CEMP) which uses many of the recommendations of the PLHRA.

Without the guidance contained in a Construction Method Statement or CEMP, the following factors would increase the risk of instability:

- construction of access tracks;
- excavation and stockpiling for foundations;
- construction of hardstanding area; and
- blocking of natural drainage, inappropriate new drainage or drainage discharge.

It is important to note that peat instability and the impacts of any instability are not constrained by artificial site or ownership boundaries but by topographic and geomorphologic boundaries. It is therefore important to ensure that the breadth of scope of any assessment adequately covers the areal extent of possible impact.

The risk assessment is based on ground models developed using a Geographical Information System (GIS) specifically for this Proposed Development. A numerical analysis was undertaken in which coefficients were allocated for each of the factors influencing peat stability.

This system outlined above was developed in accordance with the guidelines on PLHRA by the Scottish Government¹ for the investigation, assessment, and reporting for wind farms in peat areas. The analysis and interpretation are based upon the results obtained from this process as well as previous experience and the results of case studies elsewhere. Where deviations from this guidance have occurred, this is highlighted and explained in the text.

2.0 Peat Instability

The importance of assessing the stability of peat deposits in relation to renewable energy developments came to the fore as a result of peat failures during the construction of Derrybrien⁴ Wind Farm in Ireland in 2003. Although no fatalities were associated with these failures, there was a significant environmental impact. Wind farms tend to be constructed in high moorland areas which are associated with significant peat deposits (typically blanket bogs). There is a potential for peat instability to occur, particularly where deposits are in excess of 1m thick. Peat instability is influenced by many factors, including, but not limited to, peat thickness, hill slope gradient, underlying geology and subsurface hydrology.

This section reviews the nature of peat and how current and past activities can influence stability. The factors which are likely to influence the potential for peat instability are:

- Significant peat depths over impermeable bedrock or minimal soil.
- The presence of slope gradients greater than 4° (approximately) and general topography.
- Natural drainage paths.
- Evidence of past failures, including soil creep.
- Drainage features at the base of slopes which could lead to undercutting.
- Forestry plantations and artificial drainage and recent climate patterns.

It should be noted that peat instability is not a recent phenomenon and there is documentary evidence of peat landslides dating back over 500 years⁵. Many landslides that involve peat have no human interference that could be considered as a trigger, and this should be borne in mind when considering the susceptibility of a site to potential instability.

2.1 Background Information Regarding Peat

Peat is found in extensive areas in the upland and lowland regions of the UK and is defined as the partly decomposed plant remains that have accumulated in-situ, rather than being deposited by sedimentation. When peat forming plants die, they do not decay completely as their remains become waterlogged due to regular rainfall. The effect of water logging is to exclude air and hence limit the degree of decomposition. Consequently, instead of decaying to carbon dioxide and water, the partially decomposed material is incorporated into the underlying material and the peat 'grows' in-situ.

Peat is characterised by low density, high moisture content, high compressibility and low shear strength, all of which are related to the degree of decomposition and hence residual plant fabric and structure. To some extent, it is this structure that affects the retention or expulsion of water in the system and differentiates one peat from another.

Lindsay⁶ defined two main types of peat bog, raised bog and blanket bog, which are prevalent on the West coast of Europe along the Atlantic seaboard. In Britain, the dominant peatland is blanket bog which occurs on the gentle slopes of upland plateaux, ridges and benches and is predominantly supplied with water and nutrients in the form of precipitation. Blanket peat is usually considered to be hydrologically disconnected from the underlying mineral layer.

6 Lindsay, R.A., (1995), 'Bogs: The ecology, classification and conservation of Ombrotrophic Mires.' Scottish Natural Heritage, Perth.

There are two distinct layers within a peat bog, the upper acrotelm and the lower catotelm. The acrotelm is the fibrous surface to the peat bog⁷, typically less than 0.5m thick, which exists between the growing bog surface and the lowest position of the water table in dry summers. Below this are various stages of decomposition of the vegetation as it slowly becomes assimilated into the body of the peat.

For geotechnical purposes the degree of decomposition (humification) can be estimated in the field by applying the 'squeezing test' proposed by von Post and Grunland⁸ (1926). The humification value ranges from H1 (no decomposition) to H10 (highly decomposed). The extended system set out by Hobbs⁹ provides a means of correlating the types of peat with their physical, chemical and structural properties.

The relative position of the water table within the peat controls the balance between accumulation and decomposition and therefore its stability, hence artificial adjustment of the water table by drainage requires careful consideration.

2.1.1 Peat Shear Strength

In geotechnical terms, the shear strength of a soil is the physical characteristic that provides stability and coherence to a body of soil. For mineral soils such as clays or sands, such strength is variously given by an inter-particle friction value and cohesion. Depending on whether the mineral soil is predominantly cohesive (clay) or non-cohesive (sand) governs which of the components of strength control the behaviour of the soil.

For peat soils, where the major constituent is organic and there is likely to be little or no mineral component, the geotechnical definition of shear strength does not strictly apply. At present there is no real alternative method for defining the shear strength of peat, therefore the geotechnical definition is generally adopted, in the knowledge that it should be used with great caution.

As noted previously, the acrotelm or near surface peat comprises a tangle of fresh and slightly rotted roots and vegetable fibres. These roots and fibres impart a significant tensile shear strength capacity to the material which provides it with a significant load carrying capacity. The acrotelm is, in effect, a fibre reinforced soil.

In the more decomposed catotelm, the tensile shear strength is reduced as the roots and fibres become more rotted. However, the loss in strength due to decomposition is off set to a limited degree, by a gain in strength due to the overburden pressure. In geotechnical engineering there is an established relationship for recently deposited soils, between the shear strength of a sample and the thickness of overburden above it.

Consequently, it is almost impossible to predict a shear strength profile in peat and attempts to measure the shear strength using normal geotechnical methods can be misleading. Typical values of shear strength from hand shear vanes would be in the range 10-60 kilopascal (kPa) although values over 100 kPa have been recorded in peat elsewhere. The higher strengths are almost certainly the influence of roots or other non-decomposed material. It is believed that the strength of peat should be quoted as a cohesion value as there are few, if any, discrete particles to give the material a significant frictional resistance. It should be noted, however, that any quotation of shear strength for peat should be treated with extreme caution.

2.1.2 Peat Stability-Factors to be Considered

There is considerable observational information relating to debris and peat flows although the actual mechanisms involved in peat instability are not fully understood. The main influences on slope stability are geological, geotechnical, geomorphic, hydrological, topographic, climatic, agricultural and human influences such as drainage and construction activity. Peat is affected to a degree by changes in any of the above list and it is vital to appreciate that changes to the existing equilibrium would affect the level of slope stability during construction and operation of the Proposed Development.

Some of the contributory factors to peat instability are summarised as follows:

- The geographical limits which could be affected by potential instability are not confined to the artificial boundaries imposed by land ownership; landslip occurring above a site could affect the site and property down slope or downstream of the site for several kilometres.
- Agriculture and grazing have a substantial effect on peat areas, and this can be compounded in areas that have been managed to improve grazing. Grazing compacts the peat surface reducing the rainwater infiltration and the additional nutrients change the ecological balance of the original peat bog. Agricultural management can include surface drainage and periodic burning, both of which can leave the surface of the peat bare for a period of time resulting in temporary desiccation of the surface. Subsequent wetting of the peat and resumption of peat accumulation results in the former desiccated and possibly ash covered surface being incorporated into the body of the peat which introduces a weak discontinuity in the profile; this in turn becomes another unknown factor in the stability assessment.
- Forestry has a substantial effect on slope stability particularly in the early stages as the creation of a forest involves disruption of the natural equilibrium and drainage of the slopes and the installation of artificial drains by deep ploughing. The construction of access tracks further disrupts the drainage and concentrates groundwater flow into narrow, fast flowing erosive streams. The work by Winter *et al*¹⁰ noted that forest tracks can act to retard or concentrate the down slope flow of water and thus aid its penetration into the slope below. Such a mechanism has been observed at a number of recent landslips that have affected the road network in Scotland.
- Natural drainage – some of the precipitation falling onto a natural upland peat bog would be absorbed into the low permeability catotelm peat. However, most of the water would run-off as sheet flow through upper, high permeability acrotelm. Thus, the water is transmitted to the lower slopes in a reasonably controlled manner through a range of interconnections that operate at different scales and speed. Failure to understand this and to disrupt the transmission process for the groundwater could result in instability.
- Artificial drainage - where agricultural drainage has been used to improve the quality of the grazing or to promote forestry it reduces the overall volume of water entering the bog and transfers this water to the edges more rapidly. This can result in ditches and streams becoming enlarged, causing increased erosion and a greater silt burden in the stream water.

¹⁰ Winter, M.R., Macgregor, F. and Shackman, L. (2005a), 'Scottish tracks networks landslide study' Trunk tracks: network management division, published report series. The Scottish Government.

2.2 Peat Mass Stability

The principal surface indicator of peat slide potential is cracking of the peat land surface, and it is the identification of crack patterns in the field and the attendant causes of the cracking that is fundamental to a peat stability assessment.

Sites that have exhibited natural instability in the past are likely to be more susceptible to future instability during and following construction of a renewable energy development, therefore it is important to identify such instability as part of the Peat Stability Assessment.

2.2.1 Types of Failure

The result of instability in peat is the down-slope mass movement of the material; there are a number of definitions of peat instability which are used to characterise the type of failure including:

- Bog bursts or bog flows – the emergence of a fluid form of well humified, amorphous peat from the surface of a bog, followed by the settling of the residual peat, in-situ ¹¹.
- Peat slides – the failure of the peat at or below the peat/ substratum interface leading to translational sliding of detached blocks of surface vegetation together with the whole underlying peat stratum¹¹.
- Bog slide – an intermediate form of instability where failure occurs on a surface within the peat mass with rafts of surface vegetation being carried by the movement of a mass of liquid peat.

2.2.2 Bog Bursts

Accounts of bog bursts are generally associated with very wet climates or areas which have received storm rainfall events. Bog bursts can be associated with particularly wet peat landscapes; therefore, it is possible to identify broad regions of a higher susceptibility to these failures. The constraints used to identify the areas of higher susceptibility to bog burst failure are given below:

- Peat thickness greater than 2m.
- Shallow gradients, generally within the range of 2 to 5°, peat thicker than 1.5m is generally not observed on slopes steeper than 10°, also moisture content is generally reduced on steeper slopes due to drainage).
- Ground which is annually waterlogged to within the upper 1m below ground level (the groundwater level may rise above this but rarely falls below).
- Greater humification of the lower catotelm within the waterlogged ground; and lower surface tensile strength of the fibrous peat and vegetation.

The humified mass can be considered as analogous to a heavy liquid and the stability of this mass is maintained by the strength of the surface or acrotelm peat. Should the surface become weakened through erosion or desiccation or the construction of a surface drainage ditch for agricultural or forestry reasons or through turbary (peat cutting), failure is made more likely.

¹¹ Dykes, A.P and Kirk, K.J., (2001), 'Initiation of a multiple peat slide on Cuilcagh Mountain, Northern Ireland.' *Earth Surface Processes and Landforms*, 26, 395-408.

2.2.3 Peat Slides

Peat slides tend to be translational failures with a defined shear surface at or close to the interface with the substrate.

The factors generally considered to influence susceptibility to peat slide failures are listed below:

- Peat depth up to 3m;
- Slope gradients between 4.5° and 32°
- Natural or artificial drainage cut into the surrounding peat landscape
- Greater humification of the lower catotelm within the waterlogged ground
- Lower surface tensile strength of the fibrous peat and vegetation

It is noted that some of the factors causing instability are common to both bog bursts and peat slides.

The peat – substrate interface is the primary zone of failure and is enhanced by elevated water content at this boundary and softening or weathering of the lower mineral surface. For this reason, any investigation or probing should try to distinguish the nature of the lower mineral substrate.

2.2.4 Bog Slides

A bog slide is a variation on a peat slide where part of the peat mass is subject to movement, usually on an internal layer of material, which may be more prone to movement, such as an interface between the acrotelm and catotelm layer.

2.2.5 Natural Instability

The stability of a peat mass is maintained by a complex interrelationship of many factors. Key factors include sloping rock head and proximity to a water body. Rainfall often acts as the trigger after the slope has already been conditioned to fail by natural processes.

It should also be remembered that peat bogs are growing environments and that there would come a time, on sloping ground, where the forces causing instability, the weight of the bog, can no longer be resisted by the internal strength of the peat and its interface with the underlying mineral surface. At this point, failure would occur.

The weight of the peat bog or any soils mantling steep hill slopes would be increased during periods of very heavy rain and it is common to see landslips occurring following extreme rain events. This may be a concern for future developments where one of the predicted effects of global warming will be a greater frequency of extreme weather, intense storms being one element.

3.0 Desk Based Review

3.1 Site Description

The Proposed Development is located approximately 25 km west of Invergarry centred on National Grid Reference (NGR) NH 05846 02443. The Proposed Development is split into the PSH, located at Loch Fearna, and the SAR. The SAR access spans from the A87 at White Bridge which is situated to the south of Loch Garry, passes through generally commercially forested areas before traversing open moorland and crossing the River Garry further west. The final section of the access to the PSH will be along the existing public road (the C1144) which would be widened locally.

The main PSH site comprises south and south-west facing slopes and corries of upland blanket mire, heathland, and flush habitat; burns with associated riparian woodland; acid grassland, bracken, mire, and heath habitats in the lower-lying ground and a rock shingle beach along the shoreline of Loch Quoich.

3.2 Topography

From review of OS mapping, the topography across the PSH ranges from 210 to 600 m AOD. The access track to the PSH traverses northwards across steep slopes to approximately 450 mAOD, before turning east towards the PSH area. The PSH area contains Loch Fearna situated at approximately 540 mAOD. Surrounding Loch Fearna are by steep slopes and hollows on all sides. The Proposed Development extends up the slopes to the full inundation level of 600 mAOD.

The SAR is situated in a lower topographical area with gentle slopes and minor topographical highs. The western extent of the SAR, the proposed C1144 public road widening, is situated across steep, open slopes between 180 and 220 mAOD. The proposed public access route to Kingie then crosses over the River Garry onto flatter expanses at approximately 150 mAOD before traversing moderate slopes towards the commercial forestry further southeast.

3.3 Geology and Soils

3.3.1 Artificial Ground

Based on the information available from the BGS Geoindex¹², no made ground deposits are noted across the Proposed Development.

3.3.2 Superficial Geology

A review of the BGS online data¹² indicates that the PSH is largely absent of superficial soils with bedrock at or near surface. However, hummocky glacial deposits and peat are mapped across flatter expanses of the PSH area. The hummocky glacial deposits, predominantly comprised of sand and gravel, are mapped in the northern areas of the PSH, covering areas of Coire Dubh and Coire Mheil. Mapped peat deposits are situated to the south, east and localised areas of the north of Loch Fearna. In addition there is a minor area of alluvial fan deposits (gravel, sand, silt and clay) recorded bordering the eastern extents of Loch Fearna.

The majority of the SAR is underlain by hummocky glacial deposits with localised areas of mapped peat. Minor alluvium deposits, associated with watercourses are noted across the SAR.

¹² BGS Online Viewer, available at [https://mapapps2.bgs.ac.uk/geoindex/home.html?_ga=2.133433804.376188765.1646739904-1030004651.1646739904]

Figure 12.1.3 shows the superficial geology BGS mapping and the Proposed Development.

3.3.3 Bedrock Geology

A review of the BGS online data¹², indicates that the majority of the PSH is underlain by metamorphic rocks, psammities and pelites, belonging to the Lochailort Formation and the Easter Glen Quioch. The Easter Glen Quioch formation is mapped across the west, north and east of the PSH. The Lochailort Formation is predominantly mapped in the south with localised areas in the west. Several igneous intrusions belonging to the Argyll and Northern Highlands Granitic Suite are mapped across the Proposed Development, predominantly in the north and northwest near Coire Mheil and Coire Dubh with localised intrusions mapped to the southeast of Loch Fearna.

The SAR is predominantly underlain by metamorphic rocks belonging to various bedrock formations. The majority of the SAR route is underlain by the metamorphic Upper Garry Psammite Formation. In the west, the SAR is underlain by the metamorphic rocks of the Lochailort Formation and the Easter Glen Quioch. In the east, the West Highland Granite Gneiss Intrusion is mapped in the area south of Laddie Wood at Glen Garry. In addition, throughout the SAR, there are various igneous intrusive complexes mapped across localised areas of the Proposed Development including the Argyll and Northern Highlands Granitic Suite, the Ell-arkaig Dyke Swarm comprised of lamprophyres, and a group of unnamed Caledonian metamorphosed igneous rocks.

Figure 12.1.4 shows the bedrock geology BGS mapping and the Proposed Development.

3.3.4 Structural Geology

Several inferred faults, trending northwest to south-east and southwest to northeast, are recorded within the vicinity of Loch Quoich, three of which extend into the Proposed Development. In addition, there are faults recorded to the south of Loch Garry, with a major fault trending southwest to northeast present near Invergarry.

3.4 Peatland Classification

The Carbon and Peatland Map 2016¹³ indicates that most of the Proposed Development PSH is underlain by Class 3 and Class 5 peat with localised areas of Class 2 and Class 4. Class 3 peatland is the primary peatland surrounding Loch Fearna. Class 3 peatland is not considered to be priority peatland, but it is associated with wet acidic type soils where occasional peatland habitats can be found with carbon-rich soils and some areas of deep peat. Class 5 peatland is mapped across areas in the north of the PSH site across Coire Dubh and throughout areas of the Proposed PSH Track to the south of Coire Mheil. A localised area of Class 2 peatland is mapped on the descending slope to the west of Loch Fearna and throughout areas of the Proposed PSH Track descending towards the existing C1144. Class 2 peatland is dominated by priority peatland habitats where all soils are carbon-rich and deep peat. Class 4 peatland is mapped across areas of the Proposed PSH Track to the western extents of the PSH. Class 4 is unlikely to be associated with peatland habitats, wet and acidic type and is unlikely to include carbon-rich soils. In addition, Mineral soils are mapped throughout the steeper extents of the PSH, predominantly across the southern flanks of Spidean Mialach and Coire Glas, southwest of Loch Fearna and on the southern flanks of Creag Coire na Fiar Bhealaich.

Similarly to the PSH, the SAR is predominantly underlain by Class 2, Class 3 and Class 5 peatland. The western extents of the SAR is underlain by areas of Class 2 and 3 peat, whilst

¹³ NatureScot, Carbon and Peatland Map 2016, Available online at: map.environment.gov.scot/soil_maps/

the remainder of the route is predominantly Class 2 and 5. In addition, there are localised areas of mineral soils throughout the SAR and localised areas of Class 1 peat are present to the south of Loch Garry and Laddie Wood, adjacent to the Allt Ladaidh watercourse. In addition, towards the eastern extents of the SAR, there are areas of Class 4 peatland mapped.

BGS Online data¹² records indicate that there is no risk regarding the mass movement or instability of materials.

3.5 Mining and Quarrying

Information from The Coal Authority Online Viewer¹⁴ indicates that the Proposed Development is not within a coal mining reporting area.

BGS Online data¹² indicates that there are no active or historic mines or quarries within the PSH site. There are several historic pits and quarries mapped along the SAR. There are three historic pits mapped in the western extents of the SAR adjacent to the existing road C1144 and in the vicinity of the proposed switchyard and near proposed site compound 2. These pits are named the Loch Quoich Dam, Cualal nan Cabar, and the Leac Doire Lochaidh Pit – all with a status C and disused. In addition, there is a historic pit (the Lochan an Staic Quarry) mapped approximately 1km south of Loch Poulary. Towards the eastern extents of the SAR, there are various pits including the Greenfield Wood pits and the Laddie Wood Pit to the south of Loch Garry. Further east, there is one active quarry named Gleann Laogh Quarry bordering the north of the SAR.

3.6 Hydrogeology

Information from Scotland's Environment Online Map Viewer¹⁵ indicates that the Proposed Development is underlain by the Northern Highlands Groundwater body (ID: 150701) and is classified as having a 'good' overall status, as part of the most recent information available from SEPA (2020).

The PSH site is underlain by the Glenfinnan Group, whilst the SAR is predominantly underlain by the Loch Eil Group and an Unnamed Igneous Intrusion. These aquifers are all classed low productivity, indicating that small volumes of groundwater are present in near surface weathered zones and secondary fractures, and flow within the aquifer is predominantly through fractures and other discontinuities.

3.7 Hydrology

Information from SEPA's Water Classification Hub¹⁶ indicates that the Proposed Development is situated in several catchment areas. The PSH site is located within the Loch Quoich catchment. There is a network of unnamed watercourses feeding Loch Fearna, with Allt Fearna as the outflow which flows southwards and drains into Loch Quoich. In addition, there is the Allt a Mheil which flows predominantly southwards in the western extents of the PSH to Loch Quoich. There are various minor surface watercourses situated to the south of Loch Fearna which cross the Proposed PSH Track and the existing C114 road.

The SAR is situated within various hydrology catchment areas, listed from west to east:

- Unnamed tributary of River Garry DWPA

¹⁵ Scotland's Environment, Scotland's Environment Map, Available online at: <https://map.environment.gov.scot/sewebmap/>

¹⁶ SEPA, Water Classification Hub, available online at: <https://www.sepa.org.uk/data-visualisation/water-classification-hub/>

- River Kingie Catchment
- Allt Choire a Bhalachain Catchment
- Allt Lon Glas Bheinn Catchment
- Greenfield Burn Catchment
- Allt Ladaidh Catchment
- Allt na Cailliche Catchment

In the western extents of the SAR, the proposed tracks cross the River Garry which is a major river draining Loch Quoich, flowing southeast and east through Loch Garry before discharging into the Loch Oich further east outwith the Proposed Development. Throughout the remainder of the SAR, there is a series of watercourses that cross the tracks, generally associated with the River Garry and Loch Garry.

3.8 Rainfall

Periods of intense heavy rainfall are often seen as triggers for instability events. Rainfall data from the closest SEPA weather station¹⁷ at Coille Mhorgil (station number 115319), located approximately 5 km south-east of the Proposed Development, shows the monthly rainfall from in the region from October 2023 to October 2024. The highest monthly rainfall was 450.4mm recorded in January 2024.

Figure 1: Rainfall Data from Coille Mhorgil Weather Station (October 2023 – October 2024)

¹⁷ SEPA, Rainfall Data for Scotland, available online at: <https://www2.sepa.org.uk/rainfall>

3.9 Groundwater Dependent Terrestrial Ecosystems (GWDTE)

A review of the National Vegetation Classification (NVC) habitat mapping concluded that no GWDTEs have been identified to be groundwater dependent and therefore, not considered to be a potential receptor for peat instability.

3.10 Private Water Supplies and Licenced Sites

A review of the Highland Council data and previous assessments within the area of the Proposed Development indicates that there are no private water supplies (PWS) present within the PSH.

3.11 Environmental Designations

Information from Scotland's Environment Online Map Viewer¹⁸ indicates that the Quoich Spillway, classified as a Site of Special Scientific Interest (SSSI) and Geological Conservation Review (GCR), is situated in the western extents of the SAR at the Proposed Development and are situated within the Proposed Development. There are no other designated sites within the Proposed Development PSH and SAR.

The West Inverness-shire Lochs SSSI and Special Protection Area (SPA) is located 5 km downstream of Quich Dam, and approximately 1.2 km south of SAR.

3.12 Historic Instability

An area of historic instability was identified off-site, approximately 600m north of the existing C1144 public road at Leac Doire Lochaidh, National Grid Reference NH 06876 03030. This was identified by aerial imagery and was observed from the C1144. The instability was likely caused by progressive weathering and erosion of natural fractures within the rock mass. The instability has no influence on the Proposed Development but is highlighted as part of the desk based review.

Photo 1: Area of rockfall at Leac Doire Lochaidh. Taken from NGR NH 06933 02893, facing north.

3.13 Geomorphology

The Proposed Development PSH is generally characterised by upland moorland with gentle and steep slopes, corries and arêtes surrounding Loch Fearna, with flatter expanses surrounding the Loch. In addition, flatter expanses are present between breaks in slopes on the hills surrounding Loch Fearna. The PSH is absent from forestry and is generally open undulating land with frequent peat deposits, bedrock exposures and mineral soils.

The SAR is generally situated through forestry plantation in a lower topographical area with gentle slopes. The western extent of the SAR is situated across steep, open slopes in the adjacent to the PSH, which then crosses the River Garry on flatter expanses towards the forested areas further southeast.

Detailed geomorphology mapping is detailed on **Figure 12.1.5**. Typical conditions observed throughout the Proposed Development are detailed below in the following photographs.

Photo 2: View of Loch Fearna and the surrounding undulating topography with frequent bedrock exposures and peat erosional features. Taken from NGR NH 06139 03284 facing southwest.

Photo 3: View of the northern extents of Loch Fearna showing thin soils on steeper slopes, eroded peat on flatter expanses near the Loch and frequent bedrock exposures. Taken from NGR NH 06055 03020 facing northwest.

Photo 4: View of the northwestern area of the PSH towards Coire Dubh and Spidean Mialach. Taken from NGR NH 04941 03714 facing north.

Photo 5: The western area of the SAR at the River Garry crossing. Taken from NGR NH 07567 02374 facing southeast.

Photo 6: View of the Allt a Mheil valley and the crags that border the western side of Loch Fearna, showing frequent bedrock exposures. Taken from NGR NH 04701 03603 facing southeast.

Photo 7: View of the Allt a Mheil valley with frequent bedrock exposures over steep slopes and crags, with peat erosion on flatter expanses beyond. Taken from NGR NH 05260 03579 facing southwest.

3.13.1 Peat Deposits

Peat deposits are common throughout the PSH, with deposits generally associated with flatter expanses, minor slopes and hollows that allow for the accumulation and formation of peatland. The SAR has limited peat deposits with only isolated pockets of deeper peat observed in hollows. Throughout the PSH and SAR, peat deposits are generally underlain by granular glacial till material comprised of sand and gravel. Generally, where peat deposits are less than 0.5 m, it was observed that they were underlain by shallow weathered bedrock.

Peat deposits are absent from the powerhouse area located on the shores of Loch Quoich. Visual inspection and a review of aerial photography has observed that the superficial material is largely organic soils rather than peat formations.

The NVC habitat mapping indicates that M15 wet heath is the most widespread community within the Proposed Development, followed by M17 blanket bog, and M25 mire. A detailed discussion of the NVC mapping is within **Chapter 8: Terrestrial Ecology**.

No areas of instability were noted in relation to peat deposits across the Proposed Development.

Photo 8: Area of blanket bog and peat erosion located east of Loch Fearna with vegetation cover of common cottongrass and heather. Taken from NGR NH 05835 03079 facing south.

Photo 9: Thin soils underlain by granular glacial till deposits throughout the SAR, taken from NGR NN 15474 99556.

3.13.2 Peat Erosional Features

There are extensive areas of peat haggings across the Proposed Development. Peat haggings were commonly observed around Loch Fearna within the dam footprint with haggings up to 2 m in height. Peat haggings were widespread to the north and east of Loch Fearna, with haggings forming over flatter expanses and the gentle downgradient slopes of Coire Glas. Throughout areas of the proposed PSH access track, peat haggings were encountered, largely associated with the network of surface water drainage present in this area. Peat pans were encountered during surveys on the eastern slopes of Loch Fearna, where erosion of the surface vegetation has occurred resulting in bare peat exposures.

Based on site observations, peat haggings across the Proposed Development PSH is likely associated with drainage erosion due to the nature of the peat deposits being inextricably linked with the network of surface water drainage causing hydrologically influenced gully erosion. In addition, there are some areas of peatland which have been influenced by wind erosion across areas of the PSH with higher elevations and peat exposures situated on topographically exposed areas.

No areas of instability were noted in relation to any erosional features across the Proposed Development. The absence of any indications of instability and the presence of drained and actively eroding extensive peat haggings, gulleying and bare peat may indicate that the site is actually less susceptible to large scale instability and the factors utilised in the assessment within Section 6.0 are considered appropriate to determine the likelihood of peat instability at the Proposed Development.

Photo 10: Typical peat haggs encountered across the PSH, taken from NGR NH 06090 02990 looking north-west.

Photo 11: Peat located to the east of Loch Fearna, taken at NGR: NH 05930 03089 looking south.

Photo 12: Area of peat haggling associated with drainage erosion to the northeast of Loch Fearna. Taken at NGR NH 05584 03415 facing southwest.

Photo 13: Area of peat haggling with exposed underlying granular substrate and bedrock, situated to the east of Loch Fearna. Taken from NGR NH 05824 03142 facing east.

3.13.3 Artificial Drainage

Most drainage across the PSH appears nature in nature and forms dendritic drainage patterns trending towards Loch Fearna. There is no evidence of artificial drainage across the PSH. The SAR features extensive artificial drainage associated with plantation forestry with furrows trending predominantly north to south. These drainage ditches were recorded up to 1 m deep and 0.5 m wide. Throughout the areas of plantation to the north of Na Doireachan, furrows were recorded as trending east to west.

No areas of instability were noted in relation to artificial drainage across the Proposed Development.

3.13.4 Forestry

Plantation forestry is abundant across the SAR, with artificial drainage channels and furrows. Some areas of forestry have been felled.

No areas of instability were noted in relation to forestry across the Proposed Development.

Photo 14: Area of plantation forestry along the SAR, taken at NGR NN 09054 99817 facing north.

Photo 15: Area of plantation forestry and felled forestry at the SAR. Taken from NGR NN 15585 99548, facing west.

Photo 16: Area of felled forestry with overgrown furrows. Taken from NGR NN 13042 99439, facing east.

3.13.5 Bedrock

From review of aerial photography and site walkovers, there are abundant bedrock exposures and outcrops across the Proposed Development. Bedrock was frequently encountered throughout the PSH, predominantly across steep slopes and tops of ridges and peaks near Coire Dubh, Coire Glas and the ridge to the west and northwest of Loch Fearna. Across the SAR, there were minor variations in topography where bedrock exposures were encountered.

No areas of instability were noted in relation to bedrock exposures across the Proposed Development.

Photo 17: Bedrock exposures northwest of Loch Fearna, taken at NGR: NH 05257 03571.

Photo 18: Bedrock exposures in the northern area of the PSH, taken at NGR NH 04868 04042 facing north.

3.13.6 Extension/Compression Features

No evidence of any historic soil or peat failures or slides were identified across the Proposed Development from review of aerial photographs. This was confirmed during site visits where there was no evidence of any extension or compression features.

4.0 Site Work

4.1 Peat Depth Survey

Peat surveys were carried out in accordance with best practice guidance for developments on peatland^{19,20}. Phase 1 peat probing was conducted on a 100 m grid to allow for initial assessment of the Proposed Development which will be used in future preliminary site layout designs. Phase 2 probing saw detailed probing undertaken across the Proposed Development layout, focussing on access tracks, dams and other site infrastructure. Phase 2 probing was typically undertaken on linear infrastructure (permanent / temporary tracks) at 25 m to 50 m spacings with offset probing locations either side (approximately 10 m to 25 m). Infrastructure (dams, compounds, etc.) was typically probed at 10 m grid spacings.

Where surveys were undertaken by SLR, the thickness of the peat was assessed using a graduated peat probe, approximately 6 mm diameter and capable of probing depths of up to 10 m. This was pushed vertically into the peat to refusal and the depth recorded, together with a unique location number and the co-ordinates from a handheld Global Positioning System instrument (GPS). The accuracy of the GPS was quoted as ± 2 m, which was considered sufficiently accurate for this survey. All data was uploaded into a GIS database for incorporation into various drawings and analysis assessments.

Where the peat probing met refusal on a hard substrate, the 'feel' of the refusal can provide an insight into the nature of the substrate. The following criteria were used to assess material:

- Solid and abrupt refusal – rock;
- Solid but less abrupt refusal with grinding or crunching sound – sand or gravel or weathered rock;
- Rapid and firm refusal – clay; or
- Gradual refusal – dense peat or soft clay.

The relative stiffness of the peat was also assessed from the resistance to penetration of the probe and to the effort required to extract the probes (retrieval of the probe was often impossible for one person). In all instances refusal was met on obstructions allowing identification of subsurface geology.

4.2 Peat Depth

Peat is generally defined as a soil with a surface organic layer in excess of 0.5m¹⁹. Where the probing recorded less than 0.5 m thick, it is considered to be a peaty soil (or organo-mineral soil). Soils with a peaty organic horizon over mineral soil are often referred to as 'peaty soils'. These organo-mineral soils are extensive across the UK uplands, but do not meet recognised definitions of peat as they are either shallower than true peat or have a lower carbon density.

The peat was found to vary across the Proposed Development in terms of thickness and coverage. Deeper peat was generally encountered in flatter, lower gradient areas of the Proposed Development. The maximum depth of recorded peat was 3.6 mbgl, recorded at two locations, north of Loch Ferna and adjacent to the SAR. The average thickness of peat recorded across the Proposed Development was 0.4 m.

¹⁹ Scottish Renewables & SEPA (2012) 'Developments on Peatland Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste'.

²⁰ Scottish Natural Heritage (SNH), SEPA, Scottish Government & James Hutton Institute. (2014) 'Peat Survey Guidance; Developments on Peatland: Site Surveys'.

A total of 20,354 peat probes were undertaken across all survey phases, with the results summarised in Table A with all probing data provided in Annex A.

Table A: Peat Probing Results

Peat Thickness (m)	No. of Probes	Percentage (of total probes undertaken on-site)
0 (no peat or soil)	2583	12.7
0.01 – 0.49 (peaty soil)	11525	56.6
0.50 – 0.99	3692	18.1
1.00 – 1.49	1683	8.3
1.50 – 1.99	577	2.8
2.00 – 2.49	204	1.0
2.50 – 2.99	81	0.4
3.00 – 3.49	7	0.0
3.50 – 3.99	2	0.0
> 4.0	0	0.0

4.3 Peat Condition

Peat is described using BS5930²¹ and the Von Post classification²². Six peat cores and samples were collected by SLR during Phase 2, using a peat auger and used to inform interpretations of the underlying peat condition and underlying substrate. Peat samples were undertaken to depths of between 1.7 and 2.7mbgl.

The peat encountered throughout the Proposed Development was generally described as brown to dark brown, fibrous to pseudo-fibrous peat, between H2 and H4 on the von Post classification, showing insignificant to moderate decomposition. The peat encountered throughout the Proposed Development is predominantly well drained and dry with bare peat exposed in some areas that is associated with extensive peat erosion.

Peat core logs and photographs are presented within **Annex B**.

4.4 Substrate

Where possible, in the SLR investigation, an assessment of the substrate was made, as described previously. From the evidence of the probing and coring, the substrate was recorded as the following:

- Granular, recorded at 16,751 (82%) probe locations; and
- Rock, recorded at 3,603 (18%) probe locations.

Based on a review of the BGS mapping and site surveys, the granular material is anticipated to be of glacial till origin and of weathered bedrock (see **Photo 9**). No rock samples were

²¹ BS 5930:2015+A1:2020, Code of practice for ground investigations

²² Von Post, L. and Grunland, E., (1926), 'Sodra Sveriges torvillganger 1' Sverges Geol. Unders. Avh., C335, 1-127.

recovered from probe locations however, based on the observed exposures and BGS mapping, it is interpreted to be highly weathered metamorphic bedrock.

5.0 Hazard and Risk Assessment

5.1 Introduction

The Scottish Government Guidance¹ provides an overview of the principles of hazard and risk with respect to peat landslides. The guidance is noted as illustrative only and the developers can present their own methodology providing, it is clearly explained and incorporates consideration of the likelihood of instability and the consequences should it occur. The following sections detail the preferred methodology used within this assessment.

A 'Hazard Ranking' system has been applied based on the analysis of risk of peat slide as outlined in the Scottish Government Guidance¹. This is applied on the principle:

$$\text{Hazard Ranking} = \text{Hazard} \times \text{Exposure}$$

This philosophy can be applied to the assessment carried out so far in the following approach:

$$\text{Hazard Ranking} = \text{Risk Rating} \times \text{Impact Rating}$$

5.2 Methodology

The determination of Risk Rating and Impact Rating values is based on a number of variables which impact the likelihood of a peat slide and the relative importance of these variables specific to the Proposed Development.

Similarly, the consequences or Exposure to receptors is dependent on variables including the particular scale of a peat slide, the distance it will travel, and the sensitivity of the receptor.

In the absence of a predefined system, the approach to determining and categorising Risk Rating and Impact Rating is determined on a site-by-site basis. The particular system adopted for the PLHRA is outlined in the following sections.

5.3 Limitations

The detailed design and the phasing of construction works for the Proposed Development is not available at the time of writing this report. There are a number medium and high risk zones located within the receptor i.e (the proposed inundation area surface water) as shown on **Figure 12.9.1**. The inundation areas will also be subject to dewatering and existing watercourses diverted to allow for construction of the infrastructure within the PSH area essentially removing the receptor. The construction phasing of the project is yet to be determined and as such we are unable to identify when each zone would be subject to works, what they would consist of and where the potential slide risk receptor would be.

Therefore, we would propose this is covered on condition when the detailed design and phasing of the works have been proposed. We would also propose the following control measures should be adopted for potential slide risk areas during the construction phase:

- A documented procedure shall be in place and rapid reaction strategy in place prior to the commencement of construction on peat land. This strategy shall be enacted should signs of peat movement be recorded across the proposed development. This approach requires periodic and continued monitoring of the construction process by a suitably qualified geotechnical engineer.
- A geotechnical risk register (GRR) should be completed for the duration of the construction works and maintained by a suitably qualified geotechnical engineer. This documented should be updated periodically from site visits as determined by the severity of the risk.

- As part of the GRR, regular inspection and monitoring of slide risk zones should be undertaken until work within that area has been completed.
- Detailed ground investigation and slope stability analysis to be undertaken at potential slide risk zones within inundation areas by a suitability qualified geotechnical engineer.
- An on-site assessment of the potential receptors of any peat slide risk zones should be undertaken and recorded in the GRR. Mitigation measures should be proposed and documented within the same document.
- This involves with recording of any visual signs of ground movement including identification of tension cracking or slumping of peat material. Future inspection frequency would be determined post construction and be dependent upon meteorological conditions.
- Awareness of peat instability and pre-failure indicators should be incorporated in site induction and training to enable all site personnel to recognise ground disturbances and features indicative of incipient instability.

5.4 Slope Stability

The stability of peat is a complex subject and there are numerous inter-relationships that affect the stability.

A quantitative assessment requires a numerical input and such an analysis cannot account for the unquantifiable input required for a comprehensive peat stability assessment. For this reason, a purely quantitative assessment should only be considered as a guide and a qualitative assessment of stability should be used to inform the final recommendations.

The characteristics of the peat failure phenomena have been incorporated in a stability risk assessment to evaluate the risk of instability occurring within the peat areas. The main factors controlling the stability of the peat mass are the surface gradients, the depth and condition of the peat at each location and the type of substrate.

The natural moisture content and undrained shear strength of the peat are important; however, it is generally accepted that where present, the peat would be saturated and have a very low strength. It is believed to be unrealistic to rely on specific values of shear strength to maintain stability when back analysis of failed slopes indicates that there is often a significant discrepancy between measured strength in peat and stability. Shear strength has been assumed to be constant and worst case, throughout this assessment. It has also been assumed, as a worst case, that the groundwater level is coincident with the ground surface.

5.5 Risk Rating

The potential for a peat slide to occur during the construction of the Proposed Development depends on several factors, the importance of which can vary from site to site. The factors requiring considerations would typically include:

- Peat depth;
- Slope gradient;
- Substrate material; and
- Evidence of instability or potential instability;

Of these, peat depth and slope gradient are considered to be principal factors. Without a sufficient peat depth and a prevailing slope, peat slide hazard would be negligible.

The rating system outlined below differs slightly from that proposed in the Scottish Government Guidance¹ as the system adopted here incorporates three inputs compared to two in the guidance, with the potential impact of substrate added in this section.

The probability of a peat landslide 'Risk Rating' (score) was derived by multiplying the coefficients for the four key factors (with historic instability as 1) together to produce a risk rating which is a measure of the likelihood of peat instability, and this enables potential areas of concern to be highlighted. For the assessment, the following rating system was applied as shown in Table B.

Table B: Probability of Peat Landslide

Risk Coefficient	Rating	Potential Stability Risk (Pre-Mitigation)	Action
<5		Negligible	No mitigation action required.
5 - 15		Low	As for negligible condition plus development of a site-specific construction and management plan for peat areas.
16 - 30		Medium	As for Low condition plus may require mitigation to improve site conditions.
31-50		High	Unacceptable level of risk, the area should be avoided. If unavoidable, detailed investigation and quantitative assessment required to determine stability and sensitivity to minor changes in strength and groundwater regime combined with long term monitoring.
>51		Very High	Unacceptable level of risk, the area should be avoided.

5.5.1 Peat Depth

The peat depth is shown on the peat depth interpolation figures provided in **Figure 12.1.6** and **Figure 12.1.7**. The interpolation was undertaken using the Spline with Barriers tool in ArcGIS Pro) methodology.

Table C shows the peat depth ranges and their related peat depth coefficients. The ground conditions were assessed by using peat depths recorded during peat probing. Thin peat was classed as being 0.5 to 1.5 m thick, with deposits in excess of this being classed as thick. The thickness ranges used are intended to reflect the risk of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded peat less than 0.5 m thick, this has been considered to be an organic soil rather than peat and are outside the scope of this assessment.

In addition to peat thickness, the presence of existing landslip debris or indicators of meta-stable conditions such as tension cracks or slumping in the peat suggest the material is likely to become even less stable should the existing ground conditions change. Where evidence of historical slips, collapses, creep or flows is seen, a separate coefficient has been applied.

Table C: Coefficients for Peat Depth

Peat Depth Range	Description	Peat Depth Coefficients
(<0.5 m)	Peaty/organic soil	0
(0.5 – 1.5 m)	Thin Peat	2
(>1.5 m)	Thick Peat	3*

Peat Depth Range	Description	Peat Depth Coefficients
-	Slips /collapses / creep / flows	8

*Note that thicker peat generally occurs in areas of shallow gradients and records indicate that thick peat does not generally occur on steeper gradients.

5.5.2 Slope Gradients

Table D gives the coefficients applied to the categorised slope angles. The slope gradients were assessed by reference to the mapping and particularly the DTM which was used to generate a slope map (**Figure 12.1.8**), from which the gradient at each probe location could be determined and input into the risk rating spread sheet (**Annex A**). The gradient quoted at each location was based on 5 m DTM data.

Coefficients for slope gradient have been assigned to ensure the potential for both peat slides (gradients of 4-15°) and bog slides (gradients of 2-10°) are addressed. By simple inspection it is clear that steeper slopes pose a greater risk of instability than shallow gradients. Therefore, a graduated gradient scale from 0° to >12° (the practical maximum gradient on which peat is commonly observed) has been applied.

Table D: Coefficients for Slope Gradients

Slope Angle (°)	Slope Angle Coefficients
Slope <2°	1
2° ≤ Slope <4°	2
4° ≤ Slope <8°	4
8° ≤ Slope <12°	6
>12° Slope	8

5.5.3 Substrate

Table E shows the substrate type and their related substate coefficient. As noted above, most failures in thin peat layers occur at the interface with the underlying substrate; the nature of the substrate has an influence on the probable level of stability.

Peat failures often occur within glacial till deposits in which an iron pan is observed in the upper few centimetres (Dykes and Warburton, 2007)²³. They have also been observed over glacial till without and obvious iron pan, or over impermeable bedrock. They are rarely cited over permeable bedrock as the formation of peat deposits is deemed to be less likely.

Where sand and/or gravel (derived from glacial till) form the substrate, the effective strength of the interface can be considered to be good with comparatively high friction values. Under these conditions, failure is likely to occur in a zone within the peat, just above the interface. Further factors are necessary to cause a failure of this nature (increased pore pressures within the peat) and occurrence of such events is rare.

Where clay forms the interface, there is likely to be a significant zone of softening in the clay (due to saturation at low normal stresses, poor or non-existent vertical drainage and the effect of organic acids), resulting in either very low undrained shear strength or low effective shear

23 Dykes A and Warburton J (2007) Mass movements in peat: A formal classification scheme. *Geomorphology* 86, pp. 73–93

strength parameters. The result is that potential shearing could occur either in the peat, on the interface or in the clay; all three possibilities have been documented in the past.

A rock substrate provides a high strength stratum, however, the rock surface can be smooth, and, depending on the dip orientation of the strata, it can provide a very weak interface. For these reasons, at this stage, a rock interface has been given the same risk rating as clay.

Table E: Coefficients for Substrate

Substrate Conditions	Substrate Coefficients
Granular	1
Rock	2
Cohesive	3
Not proven	3
Slip material (Existing materials)	5

Probing across the Proposed Development indicated primarily granular and bedrock substrates using the refusal method. This was confirmed by coring at selected locations across the Proposed Development.

5.5.4 Results

The table of results, included in **Annex A**, shows that 20,354 probe locations were identified within the extent of the Digital Terrain Model, peat (>0.5 m) was present at 6,414 locations. The stability risk rating identified the following:

- No peat was recorded at 2,583 locations (13%), hence no risk;
- Negligible risk at 11,837 (58%) probe locations;
- Low risk at 2,757 (14%) locations;
- Medium risk at 2,671 (13%) locations; and
- High risk at 506 (2%) locations.

Figure 12.1.9 presents the interpreted risk of peat instability based on the multiplication of the risk coefficients discussed above in Table C to Table E.

5.6 Impact Rating

An assessment of the receptors 'Impact Rating' of the medium risk locations has been undertaken. It should be noted that the impact assessment is primarily concerned with impacts that affect the environment, ecology, public or infrastructure associated with the development, both on-site and potentially off-site. This assessment does not consider the detailed ecological impact of construction induced peat instability; however, the majority of the sensitive on-site receptors are the watercourses and thus the inferred ecological and environmental issues are addressed. The proposed mitigation measures in Section 6.0 would limit the potential for any slope failures into water courses and drainage features hence limit such impacts. The effect a slope failure may have on the construction site and infrastructure can be easily identified. However, the effect of an instability event on features impacted by an event not associated with the Proposed Development is harder to predict. In order to address this effect, it is not considered appropriate to assess the effect at every potential receptor location close to the Proposed Development; but rather to assess the effect a particular infrastructure feature (Dam, track, Compound, , etc.) would have on the structures or features

surrounding it. By adopting such an approach, the assessment of infrastructure features where a risk ranking of 'negligible' or 'low' (assessed in the stability risk assessments described above) is discounted from further assessment.

The impact rating coefficient (score) is derived by multiplying the receptor ranking coefficient (score) by the distance coefficient (score) and the elevation coefficient (score) for each impact receptor associated with a particular infrastructure feature. The ranking process by attributing the different weighting systems to each factor is detailed in the following sub-sections.

5.6.1 Receptor Ranking

Receptors are generally nearby structures or features that may be affected by peat movements caused during or following construction. Generally, only receptors immediately down gradient of the infrastructure feature could be affected by peat instability therefore the first phase of feature ranking requires topographic ridges and valleys to be identified across the Proposed Development and surrounding area. From this, receptors at risk from particular infrastructure features can be identified. However, should instability occur on a steep slope, there is the risk of the back scarp of the instability migrating up-slope, there-by affecting areas previously considered not to be at risk.

The main receptors located across the Proposed Development and surrounding area which could potentially be affected in the event of a peat slide; were primarily watercourses and associated tributaries, the filled inundation area (at 600 mAOD) and development infrastructure. No GWDTE or PWS have been identified as possible receptors of any potential peat instability across the Proposed Development.

Following identification of receptors at risk, these are ranked according to their size and sensitivity. Table F presents the coefficients placed on particular receptor types.

Table F: Coefficients for Receptor Ranking

Nature of Feature	Feature Coefficient
Non-critical Infrastructure (minor/private roads, tracks)	1
Critical Infrastructure & Hydrological Features (watercourses, inundation area, development infrastructure, etc.,)	3
Sub-Community (settlement 1-10 residents)	6
Community (settlement of >10 residents)	8

Based on distance to impact receptors, in this instance we have identified watercourses (which are the most sensitive receptor near the Proposed Development). The other receptors have been discounted, either they are not present or distance to receptor mitigates risk. Watercourses are the principal receptor as they are at risk of not only direct impact from a peat slide but potentially the water course creates a pathway to impact other receptors indirectly, either ecological or potential water users downstream. Based on Table F the watercourses would have an impact receptor coefficient (score) of 3 and then considering the distance to the receptor and the relative elevation differences on-site of receptors, a potential impact can be derived.

5.6.2 Receptor Proximity

The proximity of an impact receptor is also critical in assessing the likely level of disruption it may suffer following an instability event. Based on this, two further coefficients – distance from infrastructure feature and relative elevation differences between the infrastructure feature and impact receptor - are applied in deriving an impact ranking. Table G and Table H present the coefficients derived for distance and elevation of impact receptors.

Table G: Coefficient for Receptor Proximity

Distance from Coefficient Feature	Distance Coefficient
> 1 km	1
100 m – <1 km	2
10 – <100 m	3
0 – <10 m	4

Table H: Coefficient for Impact Feature Elevation

Relative Elevation of Feature	Elevation Coefficient
0 – <10 m	1
10 – <50 m	2
50 – <100 m	3
> 100 m	4

5.7 Hazard Ranking

In order to achieve a meaningful and manageable result from the hazard ranking, the results of the Risk Rating and Impact Rating have been normalised to a standard numerical scale (below).

Table I: Rating Normalisation

Risk Rating		Impact Rating	
Current Scale	Normalised Scale	Current Scale	Normalised Scale
Negligible <5	1	Very Low <10	1
Low 5 - 15	2	Low 11 - 20	2
Medium 16 - 30	3	High 21 - 30	3
High 31 - 50	4	Very High 31-50	4
Very High >51	5	Extremely High >51	5

The method of assessing probability of landslide, adverse consequence and hazard developed by SLR Consulting incorporates additional critical elements such as the substrate interface and coefficients for the receptor position, distance and elevation and as such is considered to be more rigorous than the assessment scheme proposed by the Scottish Government¹. The Hazard Ranking scale does equate to the Scottish Government¹ scale, with rankings divided over four zones.

A simple multiplication of these coefficients would result in potentially large and unwieldy risk and impact rating numbers. SLR has therefore opted to normalise these values to bring them in line with the values used in the Scottish Government Guidance¹, as illustrated in Table I.

Table J: Hazard Ranking

Hazard Ranking	Hazard Ranking Zone	Action
1-4	Insignificant	No mitigation action required although slide management and monitoring shall be employed. Slide management shall include the development of a site specific construction plan for peat areas.
5 - 10	Significant	As for Insignificant condition plus further investigation to refine the assessment combined with detailed quantitative risk assessment to determine appropriate mitigation through relocation or re-design.
11 - 16	Substantial	Consideration of avoiding project development in these areas should be made unless hazard mitigation can be put in place without significant environmental effect.
17-25	Serious	Unacceptable level of hazard; development within the area should be avoided.

The stability risk assessment has demonstrated that the majority of the Proposed Development lies within an area of negligible to low risk (84% of probe locations) with regards to stability based on **Figure 12.1.9**. 16% of probe locations identified a medium or high risk of peat instability across the Proposed Development. Following review, the majority of these locations are not considered to have either a potential impact on the development infrastructure, due to locality, either well away from influencing infrastructure, in a down gradient position or have no impact on the local watercourses (receptors). Therefore 43 medium and high risk sites have been identified and are discussed in the following section.

The stability risk assessment results presented in Table K shows the calculated hazard ranking associated with every location where there is a stability risk of medium or above, at or close to infrastructure. The particular mitigation measures to reduce the risk of instability occurring are dependent upon location and the type of proposed structure. Proposed mitigation measures and actions already undertaken to reduce the risk of peat instability occurring are also identified in Table K, together with the associated, revised hazard ranking. A more detailed discussion of the possible mitigation measures is presented in Section 6.0.

6.0 Slide Risk and Mitigation

6.1 Overview

A number of mitigation measures can be implemented to further reduce the risk levels identified across the Proposed Development. These range from infrastructure specific measures to general good practice that should be applied across the Proposed Development to increase awareness of peat instability and enable early identification of potential displacement and opportunities for mitigation.

Risks may be mitigated by:

- Undertaking site specific stability analysis using better quality geotechnical data, final design loads for infrastructure and detailed ground models in areas of specific concern.
- Precautionary construction measures – including use of monitoring, good practice and a geotechnical risk register relevant to all locations.

Mitigation measures are provided below specific to each area of “Medium” risk. These mitigation measures will also help further reduce “Low” and “Negligible” risks to potential receptors with Section 6.2 providing information on good practice pre-construction, during construction and post-construction (i.e. during operation).

6.2 Embedded Mitigation

The paragraphs below detail good practice that is recommended during construction and follow the principles detailed in the NatureScot Guidance (2024)³. These measures are considered 'embedded mitigation' for the purposes of the assessment, and have been assumed to be in place for the purposes of the assessment presented in the EIA Report:

For excavated groundworks:

- Use of appropriate supporting structures around peat excavations to prevent collapse and the development of tension cracks.
- Avoid cutting trenches or aligning excavations across slopes (which may act as incipient head scarps for peat failures) unless appropriate mitigation has been put in place.
- Implement methods of working that minimise the cutting of the toes of slopes, e.g. working up-to downslope during excavation works.
- Monitor the ground upslope of excavation works for creep, heave, displacement, tension cracks, subsidence or changes in surface water content.
- Monitor cut faces for changes in water discharge, particularly at the peat-substrate contact.
- Minimise the effects of construction on natural drainage by ensuring natural drainage pathways are maintained or diverted such that there is no significant alteration of the hydrological regime of the site; drainage plans should avoid creating drainage / infiltration areas or settlement ponds towards the tops of slopes (where they may act to both load the slope and elevate pore pressures).

For permanent tracks:

- Maintain drainage pathways through tracks to avoid ponding of water upslope.
- Monitor the top line of excavated peat deposits for deformation post-excavation.

- Monitor the effectiveness of cross-track drainage to ensure it water remains free-flowing and that no blockages have occurred.

For temporary tracks:

- Prior to the construction, setting out the centreline of the proposed track should include a walk over performed by the site manager or general foreman, along with the suitably qualified Geotechnical Engineer, and appropriate Clerk of Works. This should be carried out to check that the ground conditions / drainage paths are as expected, and “fine-tuning / micrositing” of the alignment if required.
- Weather policy should be agreed and implemented during works, e.g. identifying ‘stop’ rules (i.e. weather dependent criteria) for cessation of track construction or trafficking (e.g. allowing tracks to thaw following periods of hard frost).
- Allow peat to undergo primary consolidation by adopting rates of road construction appropriate to weather conditions.

For storage of peat:

- Ensure stored peat is not located in areas identified with ‘Medium’ or higher peat landslide likelihoods.
- Undertake site specific stability analysis for all areas of peat storage to ensure the likelihood of destabilisation of underlying peat is minimised. Analysis should consider the slope angle of the storage location, the thickness of peat being stored and being loaded and use representative parameters for both the stored and underlying peat.
- Avoid storage of peat in areas of peat >1.5 m in depth.
- Minimise haul distances for peat, storing as near to excavation as possible.
- Monitor effects of wetting / re-wetting stored peat on surrounding peat areas, and prevent water build up on the upslope side of peat mounds. Mitigate any run-off.

In addition to these control measures, the following good practice should be followed:

- A geotechnical risk register (GRR) should be prepared for the site following intrusive investigations post-consent and location specific stability analyses – the risk register should be considered a live document and updated with site experience as infrastructure is constructed.
- The locations highlighted in Section 6.2 should be included within the GRR.
- All construction activities and operational decisions that involve disturbance to peat deposits should be overseen by an appropriately qualified geotechnical engineer with experience of construction on peat sites.
- Awareness of peat instability and pre-failure indicators should be incorporated in site induction and training to enable all site personnel to recognise ground disturbances and features indicative of incipient instability.
- Monitoring checklists should be prepared with respect to peat instability addressing all construction activities proposed for site.

Monitoring during and post construction;

The following activities will be built into any monitoring of groundworks undertaken for the development:

- Ponding on the upslope side of infrastructure sites and on the upslope side of access tracks.
- Subsidence and lateral displacement of tracks.
- Blockage or underperformance of the installed site drainage system.
- Development of tension cracks, compression features, bulging or quaking bog anywhere in a 50 m corridor surrounding the site of any construction activities or site works.

This monitoring should be undertaken on a quarterly basis in the first year after construction, biannually in the second year after construction and annually thereafter; in the event that unanticipated ground conditions arise during construction, the frequency of these intervals should be reviewed, revised and justified accordingly.

- Ensure adequate drainage is maintained for any peat storage areas;
- Minimise haul distances for peat, storing as near to excavation as possible; and
- Monitor effects of wetting / re-wetting stored peat on surrounding peat areas, and prevent water build up on the upslope side of peat mounds. Mitigate any run-off.

In addition to these control measures, the following good practice should be followed:

- A geotechnical risk register (GRR) should be prepared for the Proposed Development following intrusive investigations post-consent and location specific stability analyses – the risk register should be considered a live document and updated with site experience as infrastructure is constructed.
- All construction activities and operational decisions that involve disturbance to peat deposits should be overseen by an appropriately qualified geotechnical engineer with experience of construction on peat sites.
- Awareness of peat instability and pre-failure indicators should be incorporated in site induction and training to enable all site personnel to recognise ground disturbances and features indicative of incipient instability.
- Monitoring checklists should be prepared with respect to peat instability addressing all construction activities proposed for site.
- A documented procedure shall be in place and rapid reaction strategy in place prior to the commencement of construction on peat land. This strategy shall be enacted should signs of peat movement be recorded across the proposed development. This approach requires periodic and continued monitoring of the construction process by a suitably qualified geotechnical engineer.
- A detailed Construction Environmental Management Plan (CEMP) shall be produced and incorporate the conclusions of the peat stability report, continuously update the assessment and develop appropriate mitigations to respond to the peat slide risk as development proceeds.
- As part of the geotechnical risk register (GRR), regular inspection and monitoring of stored peat should be undertaken until temporary storage has been completed. This involves with recording of any visual signs of ground movement including identification of tension cracking or slumping of peat material. Future inspection frequency would be determined post construction and be dependent upon meteorological conditions.

- Awareness of peat instability and pre-failure indicators should be incorporated in site induction and training to enable all site personnel to recognise ground disturbances and features indicative of incipient instability.

6.3 Proposed Mitigation

As noted in **Figure 12.1.9**, where the risk assessment has identified a negligible or low risk of peat instability, no specific mitigation measures are necessary. However, in order to ensure best practise is employed, there would be a need for careful monitoring and the construction management must include careful design of both the permanent and temporary works appropriate for peat soils; as detailed in Section 6.2.

The areas of the infrastructure that were rated as medium or high risk, or above, were subjected to a hazard assessment; a number of areas were discounted as they do not fall within influencing distance of any of the key proposed site infrastructure. The procedure adopted was to review the peat slide risk data and identify those areas with a medium risk or greater, that were in close proximity or influencing distance of any of the proposed infrastructure or watercourses. Those risk areas where there is no development would not affect the natural stability of the peat.

Table K lists the locations that have been identified to have a medium risk of peat instability on the Proposed Development infrastructure. A variety of mitigation measures are recommended to reduce the risk of peat instability. Analysis of each location has shown that all can be mitigated to a Hazard Ranking of “Insignificant”.

Table K: Risk Register

Location	Risk Rating	Impact Rating	Hazard Ranking	Infrastructure at Risk Zone	Key Receptor	Mitigation	Revised Hazard Ranking
1	High	High	Substantial	Inundation area	Inundation area	Risk location largely absent of peat >0.5m only localised pockets of peat between 0.5 to 1m are present up-slope of the proposed inundation level. Risk of peat mass failure is unlikely in this area due to negligible peat deposits. Excavation of peat prior to construction would reduce and mitigate risk of peat landslide to the south. Suitable shoring of excavations would assist in mitigating risk during construction. Catch wall ditches or fences could be constructed downslope of the risk location to mitigate against any peat slide during or post construction. Benching of slopes along tracks would also mitigate against risk. Drainage pathways should be maintained during and post construction to reduce risk of peat slide. Good construction practices, as detailed in the Section 6.2, should be followed to mitigate against any instability.	Insignificant
2	High	Low	Significant	Inundation area	Inundation area	Risk location largely absent of peat >0.5m only localised pockets of peat between 0.5 to 1m are present up-slope of the proposed inundation level. Risk of peat mass failure is unlikely in this area due to negligible peat deposits. Excavation of peat prior to construction would reduce and mitigate risk of peat landslide to the south. Suitable shoring of excavations would assist in mitigating risk during construction. Catch wall ditches or fences could be constructed downslope of the risk location to mitigate against any peat slide during or post construction. Benching of slopes along tracks would also mitigate against risk. Drainage pathways should be maintained during and post construction to reduce risk of peat slide. Good construction practices, as detailed in the Section 6.2, should be followed to mitigate against any instability.	Insignificant
3	Medium	Low	Significant	Inundation area	Inundation area	Risk location largely absent of peat >0.5m only localised pockets of peat between 0.5 to 1m are present up-slope of the proposed inundation level. Risk of peat mass failure is unlikely in this area due to negligible peat deposits. Excavation of peat prior to construction would reduce and mitigate risk of peat landslide to the south. Suitable shoring of excavations would assist in mitigating risk during construction. 7.0 Conclusion

The report has highlighted the complicated inter-relationship between all the aspects that have an effect on the stability of peat. Consequently, the discussion has also addressed areas of construction and drainage in order to avoid a stability problem rather than attempt to put it right after the event. The Proposed Development has been assessed for potential hazards associated with peat instability; the assessment has been based on:

- A walk-over survey by an experienced geologist;
- A thorough inspection of the digital terrain map;
- Review of historical and geological maps and publications and aerial photography; and
- A detailed geotechnical probing exercise at 10,641 locations in areas of identified peaty soil/peat to determine the thickness thereof.

Peat probing fieldworks have indicated that 68% of peat probe locations encountered <0.5 m of peat. 27% of probe locations identified peat between 0.5 to 1.5 m, and the remaining 4% of probe locations encountered peat depths >1.5 m. The PLHRA method has been developed by SLR and described within this report. The results indicate that 15% of probe locations are at medium risk of peat instability.

The overall conclusion regarding peat stability is that there are areas of medium or high risk of peat instability across the Proposed Development and most have these have been avoided during the design process. For the remaining 43 medium or high risk areas, a hazard impact assessment was completed which concluded that, with the employment of appropriate mitigation measures, all of the areas can be considered as posing an insignificant risk.

Regardless, additional mitigation measures have been identified in areas where hazards are already considered insignificant to further reduce the risk of potential hazards occurring.

This report should be considered as the first stage in the development of a fundamental understanding of the various inter-relationships that govern and control the peatlands at the Proposed Development.

The commissioned assessment has purposefully kept the extent of physical intrusion into the sensitive peat areas to an absolute minimum. The results are considered appropriate to support a planning application.

Good construction methods and appropriate micro-siting (at detailed design stage) would also be effective at controlling residual peat landscape risk for lower risk locations at the Proposed Development. Providing that the recommended mitigation measures are put in place and adhered to, the risk of peat landslide as a result of the Proposed Development is assessed as not significant.

More detailed ground investigations will be required to support the geotechnical design stage of the Proposed Development. This will be incorporated into the Construction Method Statement which will be submitted to the Planning Authority for approval as part of the condition compliance prior to any site works commencing.

Annex B Peat Coring Data

Technical Appendix 12.1: Peat Landslide Hazard Risk Assessment

Fearna Pump Storage Scheme

Fearna Storage Limited

SLR Project No.: 428.013125.00001

Hole No.

PC01

Sheet 1 of 1

[illegible]

Remarks:

1. Peat core obtained using peat sampler.

Hole No.

PC02

Sheet 1 of 1

[illegible]

Remarks:

1. Peat core obtained using peat sampler.

		Peat Core Log						Hole No. PC03 Sheet 1 of 1	
Project: Fearna Pump Storage Scheme				Client: Fearna Storage Ltd.				Dates: 20-07-2023	
Project No: 428.013084.00001				Logger: ET		Approved By: AH		Coordinates: E: 205439.00 N: 803773.00	
Location: Invergarry, Highlands				Hole Type: HA		Level:		Vertical Scale: 1:26	
Water	Depth (m)	Sample Type	Depth	Recovery (%)	Depth (m) / Discontinuity Detail	Level (mAOD)	Legend	Stratum Description	
	0.00 - 1.00			Recovery = 90%	0.50			Dark brown pseudo-fibrous PEAT (H2, B2)	1
							Dark brown pseudo-fibrous PEAT (H3, B2)		
	1.00 - 2.00							2	
	2.00 - 2.70						Dark brown pseudo-fibrous PEAT (H4, B2)		
				Recovery = 85%	2.00				
				Recovery = 100%	2.70			Peat Core Complete at 2.70m

	0.00 - 1.00			Recovery = 90%	0.30			Brown fibrous PEAT (H2, B2)	1		
								Dark brown pseudo-fibrous PEAT (H3, B2)			
	1.00 - 2.00				1.00			Dark brown pseudo-fibrous PEAT (H4, B3)		2	
	2.00 - 2.40				2.40						3
						Recovery = 100%					Peat Core Complete at 2.40m
									5		
Remarks: 1. Peat core obtained using peat sampler.											

Hole No.

PC06

Sheet 1 of 1

Project: Fearna Pump Storage Scheme	Client: Fearna Storage Ltd.	Dates: 20-07-2023
-------------------------------------	-----------------------------	-------------------

Project No: 428.013084.00001	Logger: ET	Approved By: AH	Coordinates: E: 205576.00 N: 802805.00
------------------------------	------------	-----------------	--

Location: Invergarry, Highlands	Hole Type: HA	Level:	Vertical Scale: 1:26
---------------------------------	---------------	--------	----------------------

Water	Depth (m)	Sample Type	Depth	Recovery (%)	Depth (m) / Discontinuity Detail	Level (mAOD)	Legend	Stratum Description	
	0.00 - 1.00			Recovery = 100%	0.50			Dark brown fibrous PEAT (H2, B2)	1
								Dark brown pseudo-fibrous PEAT (H3, B2)	
	1.00 - 2.00			1.50			Dark brown pseudo-fibrous PEAT (H4, B2)	2	
				2.20			Peat Core Complete at 2.20m		
	2.00 - 2.20					Recovery = 90%			
			Recovery = 100%
